Bad Faith and the Unconscious
Jonathan Webber

Self-deception is a complicated and puzzling phenomenon (see self-deception). How is it possible to actively hide something from yourself? Philosophers find this question interesting for two main reasons. One is that the answer promises to be informative about the mind more generally, or at least it seems that any theory of the nature and structure of the mind that cannot account for self-deception must be wrong. The other is that the ethical concern with how one should live and the more specific moral concern with right and wrong actions seem to require us to evaluate our own lives and those of others in an honest and unprejudiced way, a requirement we would be better equipped to fulfill if we had a clear idea of the ways in which self-deception about these things can occur. There have thus been major philosophical discussions of the nature of self-deception in both the anglophone and the European traditions of philosophy over the past century. However, these two traditions of thought have taken crucially different examples as their paradigms of self-deception.

Recent anglophone discussion has focused on the idea that one can deceive oneself into believing something. Self-deceptive belief seems paradoxical because of the features that distinguish deception from mere error. If you deceive me, then you bring me to believe something that you know to be false, something that you merely believe to be false, or something about the truth or falsity of which you have no real opinion. How can you bring yourself to believe something that you do not believe? Can you inculcate in yourself a belief that is sufficiently robust to survive the continuing lack of evidence in its favor, or even the continuing presence of evidence against it?

Theories of self-deception in twentieth-century European thought, by contrast, have focused on the idea that one can hide one's own motivations from oneself. At the heart of Sigmund Freud's psychoanalysis is the idea that behavior can be motivated by drives and impulses whose existence the agent cannot become aware of without the help of a psychoanalytic procedure (see Freud, Sigmund). As the psychoanalyst comes close to uncovering these motivations, according to Freud, the person whose motivations they are tends to resist. Such motivations are not merely "descriptively unconscious," in Freud's terminology; they are not merely motivations of which the agent is unaware. They are "dynamically unconscious," motivations that the agent actively tries to keep out of conscious awareness (Freud 1923: Chs. 1 and 2; see also Freud 1915: §2). This resistance is itself psychologically puzzling. Freud is describing people who have sought the help of a psychoanalyst to uncover the motivations underlying the behavior that troubles them. Why, then, do they avoid awareness of those motivations? It seems that either their motivation for repressing these drives and impulses or their real motivation for seeking psychoanalytic help must also be
hidden from them. This idea that one can spin a complicated web of internal deceit about one’s motivations underwent various transformations during Freud’s career. But it remained an architectonic element of his own psychoanalytic theory and of those of his followers, including most notably Melanie Klein.

The main opposing view in twentieth-century European thought is Jean-Paul Sartre’s theory of bad faith (see Sartre, Jean-Paul). Sartre agrees that people have the capacity to conceal from themselves their own motivations, that they generally do exercise this capacity, that doing so can create complicated webs of internal deceit, and that one can do it so successfully as to require the help of a psychoanalyst to uncover one’s own motivations (Sartre 1943: Part IV, Ch. 2, §1). But Sartre does not agree that this is best explained by the Freudian picture of a dynamically unconscious activity of repression and resistance. He argues that such an account ultimately fails to explain the phenomenon of self-deception (1943: Part I, Ch. 2, §1). Neither does he agree with Freud’s theory of the basic drives and impulses that underlie our behavior and that we often repress. He considers Freud to have cut off the explanation of behavior at an arbitrary point (1943: 656, 659–60; cf. Sartre 2018 [1943]: 737–8, 741–3). These criticisms lead Sartre to offer his own account of self-deception, which attributes it to bad faith.

The disagreement between Freud and Sartre concerns one’s ability to prevent oneself from forming true beliefs about one’s own motivations. This ability does not require the inculcation of false beliefs, since one might simply form no relevant beliefs at all. The central topic in the recent anglophone discussion of self-deception is therefore extraneous to the disagreement between Sartre and Freud. But it would be a mistake to infer from this that the two issues are entirely independent of each other. For any account of self-deceptive belief formation needs to explain how one manages to keep one’s motivation to deceive oneself hidden from oneself. After all, nobody will be deceived when they are aware of the would-be deceiver’s motivation. In order to deceive oneself, therefore, it seems that one must be ignorant of one’s motivation to deceive oneself. Of course, one can generally act on a motivation without forming a belief about that motivation. But self-deception seems to require something stronger: that one can hide one’s motivation from oneself, prevent oneself from easily forming the belief that one has that motivation. Whereas one’s ability to hide one’s motivations does not require that one be able to deceive oneself into holding a particular belief, the converse is not true. Self-deceptive belief formation does require that one be able to hide one’s motivation from oneself.

For this reason, contemporary anglophone philosophical discussion of self-deceptive belief would do well to draw on the careful and detailed theories of self-deception about motivation developed by Freud and Sartre. Neither of these thinkers, however, ever presented a clear and distinct account of this aspect of their theory of mind. Freud’s theory of repression and resistance was in continuous development throughout his long career. Sartre’s critique and alternative proposal develop across his career, though the basic structures remain those presented in Being and Nothingness. As a result, discussions of each of these thinkers, and of their disagreement on self-deception, present a variety of different pictures. In the case of Freud,
this is largely due to some unclarity in the detail of his theory and presentation that makes it difficult to read his works through the lens of more recent views about the mind (Gardner 2000).

In Sartre’s case, on the other hand, unclarity goes hand in hand with his readers’ tendency to assume that *Being and Nothingness* is a sequential treatise that establishes views on distinct topics in each chapter by building on previous ones – when in fact it progressively elaborates a single theory, none of the aspects of which is fully explained until the end. Discussions of Sartre’s response to Freud tend to focus on one relatively short early section entitled “Bad Faith and Lies” (Sartre 1943: Part I, Ch. 2, §1) and ignore the richer and more nuanced discussion toward the end, in the section “Existential Psychoanalysis” (Sartre 1943: Part IV, Ch. 2, §1). And this later discussion can be fully appreciated only in the light of much of the preceding argument – though it is also illuminated by the discussion of Freud in Sartre’s earlier book, *Sketch for a Theory of the Emotions* (Sartre 1939: §2).

As a result of the general misunderstanding of the structure of Sartre’s book, the opposition between the Freudian and the Sartrean accounts of self-deception is often mischaracterized, Sartre being portrayed as balking at Freud’s rejection of certain tenets of the Cartesian view of the mind. In his theorizing about the dynamic unconscious, Freud has described some sort of purposive mental activity that occurs in a mechanistic fashion, without any self-awareness. According to the standard reading, Sartre wants to retain the identification of mentality with consciousness and to retain the dualistic denial that anything mechanistic could be part of the mind. Sartre’s own descriptions of self-deceptive behavior may be illuminating, it is argued, but the full range of self-deceptive strategies and the complexities of the human mind cannot be understood unless we abandon these Cartesian shibboleths, as Freud has done (e.g., Soll 1981; Neu 1988).

It is unfortunate that this reading of the early stages of *Being and Nothingness* exercises such influence over the understanding of the disagreement between Freud and Sartre. For the sophisticated discussion of Freud toward the end of Sartre’s book draws on intervening chapters that repudiate the idea that mentality is to be identified with consciousness, as is usually understood, and that we cannot understand the human mind unless we see it as constituted by the living human body (see esp. Sartre 1943: Part II, Ch. 1, §§1–5; Part III, Ch. 2, §1). As we will see, the disagreement between Freud and Sartre is precisely the opposite of what it is usually presented to be. Sartre is attracted to Freud’s insights but considers the Freudian account to retain an unacceptable vestige of the Cartesian view of the mind: a dualistic opposition between rational thought and mechanistic drives and impulses. Sartre presents a more comprehensive rejection of Cartesian dualism than does Freud.

Freud’s understanding of the mind rests on a distinction between two kinds of mental item (1923: Chs. 1–2; 1915: §§5–6). Items in one of these categories are sensitive to evidence about the nature of reality, are inferentially and evidentially related to one another, and are thereby available for beliefs to be formed about them, beliefs that can then be communicated. Items in the other category do not stand in a rational relation to one another or to anything else. They are drives and impulses that
combine and compete according to the laws of their “cathetic energy.” Items of this kind can motivate actions that aim to satisfy them. So the sex drive, for example, is manifested in sexual activity. This is unproblematic so long as the person accepts the drive and can reasonably engage in the behavior that would satisfy it.

Repression is the refusal to allow a drive to play its part in one’s behavior. Freud sees this repression as a form of self-deception. According to him, repression typically involves denying that one possesses the troublesome drive or impulse rather than acknowledging its presence. The repressed drives are dynamically unconscious. Because the person will not allow actions aimed at satisfying them, these drives are manifested in actions that merely symbolize them. An illicit sexual desire, for example, might be manifested in some other illicit action that the person does not really desire in itself, such as petty theft of items the person does not even want (e.g., Freud 1915: §§4 and 7). This is why repression can lead to behavior whose root causes cannot be uncovered easily without the aid of psychoanalysis.

Sartre’s “Bad Faith and Lies” is devoted to arguing that Freud’s distinction between two kinds of mental item cannot explain self-deception. For the activity of repression involves recognition of the drive as something to be repressed and the recognition of the actions aimed at satisfying it, while the activity of resistance involves comparison of the psychoanalyst’s suggestion about the repressed drive with the repressed drive itself. These are rational activities. Repression and resistance, therefore, cannot be the product of nonrational drives. They consist in mental processing of the first kind, involving items that are sensitive to evidence, inferentially and evidentially interrelated, and available for beliefs to be formed about them and communicated. In this case, the activities of repression and resistance would be as consciously available as any other aspects of the mind.

The problem is that self-deception requires that one hide the self-deceptive activity from oneself. So, for repression and resistance to be forms of self-deception, one would have to be able to deceive oneself about one’s engagement in these activities. Nothing in Freud’s account explains this possibility: Freud’s account characterizes the things about which we deceive ourselves as being beyond the reach of rational inference; but the activities of repression and resistance cannot themselves be beyond the reach of rational inference, because they involve such inference. Moreover, it is difficult to see how Freud’s theory could be augmented to accommodate this. It would not be enough to argue that repression and resistance can occur in the absence of some further condition required for conscious accessibility: one would have to argue that one can actively maintain the absence of that condition while preventing oneself from being aware of doing so, which just raises the problem of self-deception in another place.

Freud’s departure from the Cartesian understanding of the mind consists in his denial that the mind is made up solely of consciously accessible, informationally sensitive, inferentially available, linguistically articulable items. The drives and impulses that he discusses are genuine parts of the mind rather than merely aspects of the body, because they carry information that influences the operation of the rest of the mind (Freud 1915: §1; 1923: Ch. 1). Yet these parts operate, in Freud’s theory, according to
mechanical laws of causality rather than rational laws of thought. Freud has abandoned the Cartesian idea that mind has informational content that operates according to the laws of rational inference, whereas everything else lacks such content and operates mechanically. But he has not done so by rejecting the dualism of reason and non-rational causality; neither has he rejected the dualism of the informational and the noninformational; and, of course, he has not rejected the dualism of the conscious and the unconscious. He has simply denied that these three dualisms coincide.

Freud's conception of the mind draws a boundary between the informational and the noninformational: everything within the mind represents either the world beyond the mind or some goal to be achieved. This boundary does not coincide with the one between the consciously accessible and the consciously inaccessible: some mental items are consciously accessible, some are dynamically unconscious. Neither does it coincide with the boundary between the rational and the mechanical: some mental items operate rationally, some operate mechanically. Most importantly, the boundary between the conscious and unconscious does not coincide with the boundary between the rational and mechanical: all rationally structured items in the mind are consciously accessible; some purely mechanical items are consciously accessible, but others are dynamically unconscious. Cast in this light, it is clear just how much of the Cartesian picture is actually retained by Freud. It is also clear just where Sartre's criticism bites: since self-deception is an intelligent activity, it cannot be part of the purely mechanical aspect of the mind; since it is not immediately available for inference and articulation, it cannot be part of its rational aspect either.

Sartre's departure from Freud is to deny that behavior can be traced back to drives and impulses that cannot be analyzed and explained in terms of the individual's own choices or preferences and are not responsive to the consciously accessible aspect of mind. These are “pseudo-irreducible” items, claims Sartre; it is simply arbitrary to accept them as basic (Sartre 1943: 656, 659–60; 2018: 737–8, 741–3). By denying that there are any such motivations, Sartre denies the dualism of reason and mechanism that Freud's account rests on. But he does not deny this dualism simply by excluding one side of it from the mind. He does not agree with Descartes that the mind should be identified with what Freud considered to be its inferential aspect. Neither does he attempt to show that the mind is entirely mechanical. His strategy is to present a new account of the mind, one that does not draw this dichotomy in the first place.

Sartre's theory of mind gives a central role to the idea of a “project” (projet). A project need not be aimed at bringing about something that is not yet the case; staying alive can count as a project. Neither need a project be concerned directly with the sort of person one wants to become, though of course a corollary of any project is that one becomes the person who pursued that project. Writing a book is a project whose direct aim is the writing of the book, although this brings with it that one becomes the person who wrote that book. One can engage in intelligent behavior guided by a project, moreover, without any explicit awareness of doing so, as when one walks a familiar route while thinking about some difficult problem one needs to solve. Finally, a project can be pursued as a constitutive part of the pursuit of another project. Walking that familiar route might be the pursuit of the project of getting to
the office where one works, which itself is a way of pursuing the project of keeping one's job, which is a way of ensuring that one stays alive and healthy (Sartre 1943: 512; 2018: 574).

A project is an undertaking. It is something the person has committed to and remains committed to. But it is also a matter of habit. As one has actively pursued the project of staying alive for some time, many of the things one does to stay alive and healthy will have become so habitual that one might never really consider why one does them or whether it is worth continuing. One just feels the need to eat, the need to sleep, the need to get to work on time, and responds accordingly. But this does not mean that one's behavior is not goal-directed, or that one does not endorse the goal to which it is directed. It is just that one no longer thinks about it.

That one can pursue a project without thinking about it is only part of the Sartrean account of self-deception about one's motivations. For self-deception, as we have seen, requires the stronger point that one can hide this motivation from oneself in such a way that it becomes at least very difficult for one to see that it is one's motivation. This aspect of Sartre's theory of self-deception rests on his account of the way in which projects influence behavior. Their role is to structure experience. The world as one experiences it, according to Sartre, is a world of invitations, demands, prohibitions, tools, and obstacles whose practical status is dependent on the projects that one pursues. This is what Sartre means by the term "situation": one's experience reflects one's own goals and values (1943: 76–7; 2018: 78). In responding to things as they seem, one serves one's own priorities. When one feels the need to eat, the need to sleep, the need to get to work on time and one responds accordingly, one is pursuing one's project of staying alive. It is not just one's awareness of one's surroundings and bodily states that is structured in this way, according to Sartre; all of one's experience is so structured, even one's consideration of one's own thoughts and motivations.

It is this aspect of the idea of a project that allows one to pursue projects that manage to conceal themselves. Sartre's central example in *Being and Nothingness* is the inferiority project. The goal of this is to present oneself to oneself and others as intrinsically inferior to other people. Sartre claims that pursuing this project involves adopting further projects that one cannot hope to achieve, or that one pursues in hopeless ways, so that when one fails to achieve these goals one can blame one's natural inferiority (1943: 550; 2018: 616). This requires one to consider oneself to be genuinely attempting to achieve those other goals, since otherwise the failure to achieve them will not feel like genuine failure. The inferiority project must structure one's experience such that certain goals seem achievable when they are not, or seem achievable by means that will not in fact bring them about. It must also structure one's experience such that one seems to oneself to be genuinely pursuing those goals. One would then be unlikely to recognize that one is pursuing the project of proving oneself inferior; one would seem to oneself to be genuinely pursuing other projects and failing at them. It would take a detached analysis of one's overall pattern of behavior to identify the problem.

One central disagreement between Freud and Sartre, therefore, concerns the relation between the motivations that are hidden and the behavior that they motivate.
Freud sees this relation as one of symbolization. Sartre, on the other hand, sees the behavior as genuinely a way of pursuing the hidden goal (1939: §2). Whereas petty theft might symbolize some illicit sexual act, as Freud claims, it is not a way of pursuing that sexual goal. Trying to become a concert pianist without formal piano tuition, however, is a way of pursuing the goal of failing in one's projects and so showing oneself to be inferior to other people. This illustrates the deeper difference between the two accounts. On the Freudian view, self-deception about some motivation is an activity that is only contingently connected to that motivation. It is because one disapproves, usually because society disapproves, of that motivation that one hides it from oneself. On the Sartrean picture, however, it is in the very nature of the motivation that it must conceal itself if its goal is to be achieved. One will not succeed in persuading oneself of one's inferiority if one is clearly aware that this is one's goal.

Sartre thinks that the capacity for self-deception about one's motivations shows us something fundamental about the mind. It shows us that conscious experience and consequent practical reasoning are already structured by the agent's projects (see practical reasoning). This is how it is possible for those very projects to be beyond easy inferential reach. Sartre's view of the mind is a bold rejection of the traditional philosophical view that practical reason involves rationally weighing considerations in order to formulate one's goals. One's prior projects, according to Sartre, determine which considerations will occur to one and how they will be weighted. This aspect of Sartre's philosophy is in line with current thought across social psychology. Research programs into the psychology of attitudes, goals, schemas, and values are converging on the view that one's prior commitments influence which factors in the current situation are taken into consideration and what significance they hold in deliberation.

However, it is not clear that this aspect of Sartre's philosophy is consistent with his theory that one's projects have no inertia or weight of their own, but simply persist only because one continues to endorse them. The research programs in social psychology suggest that one's commitments become progressively more embedded in one's cognitive system the more they are employed in reasoning and action. The more weight or inertia a commitment has accrued through this process, the greater its influence over cognition and action. If this theory is right, then Sartre's famous conception of “radical freedom,” the freedom to replace one's projects at any time, is mistaken. Indeed, this idea that the fundamental commitments of the mind are immediately responsive to rational revision looks rather like a vestige of the Cartesian dualisms that Sartre has officially abandoned. The picture emerging from social psychology rather supports Simone de Beauvoir's theory, most clearly expressed in The Second Sex, of the progressive sedimentation of projects (see de beauvoir, simone; de beauvoir 1949 II: Part 1, Ch. 1; II: Part 2, Ch. 10; webber 2018: §4.2, §§4.4–4.6, §5.6, §§11.2–11.4).

De Beauvoir's version of the idea that one's outlook is shaped by one's projects affords a theory of self-deception that is distinct from the idea of bad faith. For it allows that one is genuinely misled by the projects that have become sedimented into one's own outlook (webber 2018: §5.7). But this seems consistent with the
Sartrean idea that the same structures can also support a more purposive form of self-deception about one's own motivations. We have seen that self-deception about belief seems to require self-deception about one's motivations. If the existentialist view of the structures of self-deception is correct, then perhaps the project-based view of the mind that requires it can also explain the capacity for self-deceptive belief.

It is a further question what the ethical implications are of our capacity for self-deception. Psychology alone cannot formulate ethical precepts, but it does constrain ethics in two ways. It constrains the moral psychology involved in normative ethical theories (see moral psychology). Much of modern ethics, particularly utilitarian and Kantian accounts of morality, seems to assume that actions are generated through consciously accessible and rationally structured deliberation. If such an assumption cannot be incorporated into any theory of motivation capable of explaining our capacity for self-deception, then it seems that these theories will need to be revised, or perhaps entirely discarded. Psychology also constrains the practical outcomes of moral theorizing. There is no point in simply exhorting people to act on the right kinds of motivations if their own motivations are often opaque to them. Similarly, there is no point in critical self-reflection if one is likely to distort the evidence to fit one's favored self-image. The ethical task of becoming a better person is partly a task of self-knowledge (Cottingham 2010). If ethics is to be concerned with motivations at all, therefore, practical ethical prescriptions ought to include procedures for uncovering and assessing fairly those motivations as well as some method for changing them. Precisely how our capacity for self-deception constrains theories of moral psychology and practical ethics, of course, depends on how that capacity is best understood.
